1. Introduction

This Document describes the design for the TaskFlow application. TaskFlow is a web-based application intended to help users track assignments, chores, or responsibilities through the creation of task card objects.

As software design and architecture is often complex, multiple diagrams have been presented to better express this application's design. This document includes a logical, high-level view, a mid-level view, and a detailed class design view.

2. Design Goals

Our design is measured by the usefulness and intuitiveness of the application by the users. With students intending to be a large majority of users, design goals were created and prioritized in regards to student population when it comes to application use.

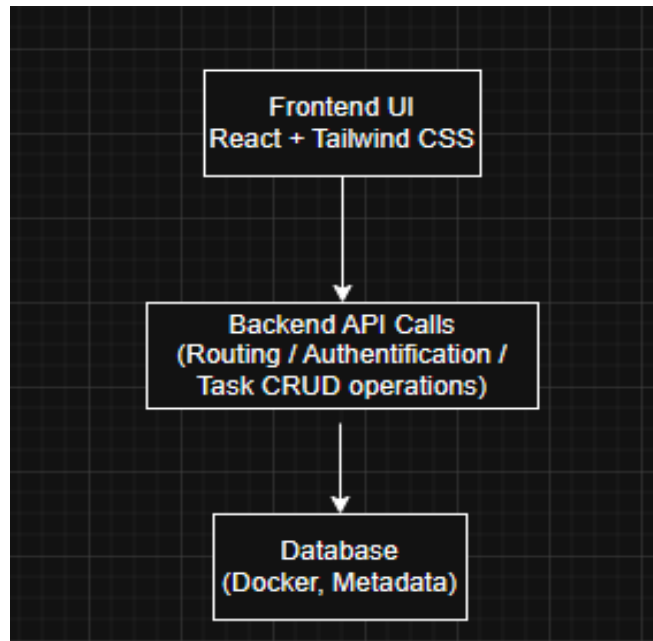

Priorities for design include:

- The design should minimize development time by reducing complexity
- The design should implement a clear, easy to navigate, and minimalistic UI to support users juggling multiple tasks
- The design should consider the project deadline as well as the team size to determine project scope
- The design should be adaptable and allow for easy additions after the initial launch of the application
- The design should allow for reusable components for potential UI modification

3. Design Views

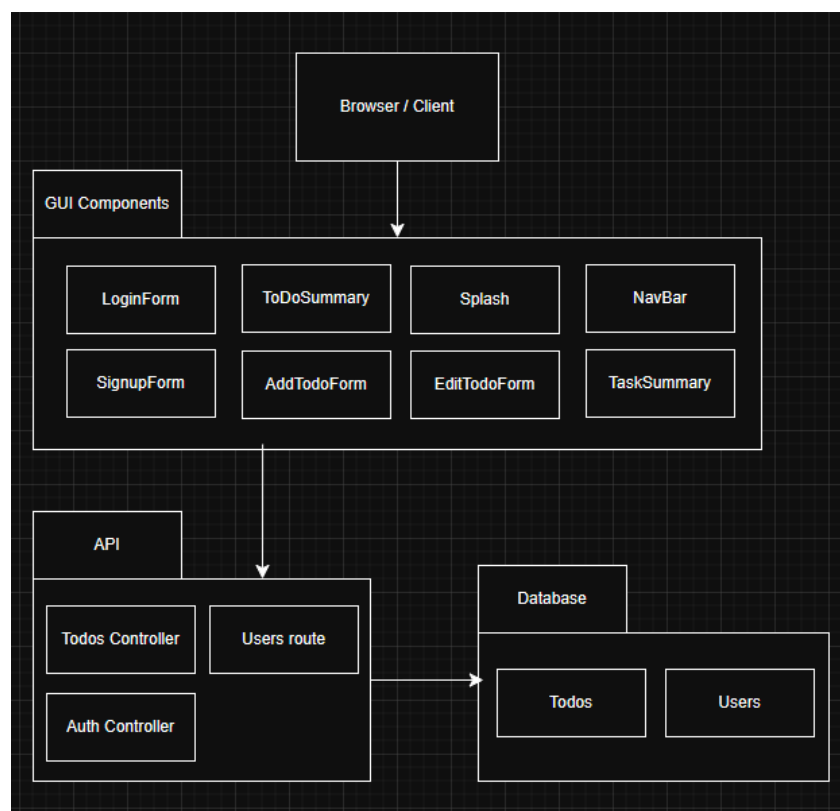

3.1 High Level Design

The High Level view of the program consists of only three major components:

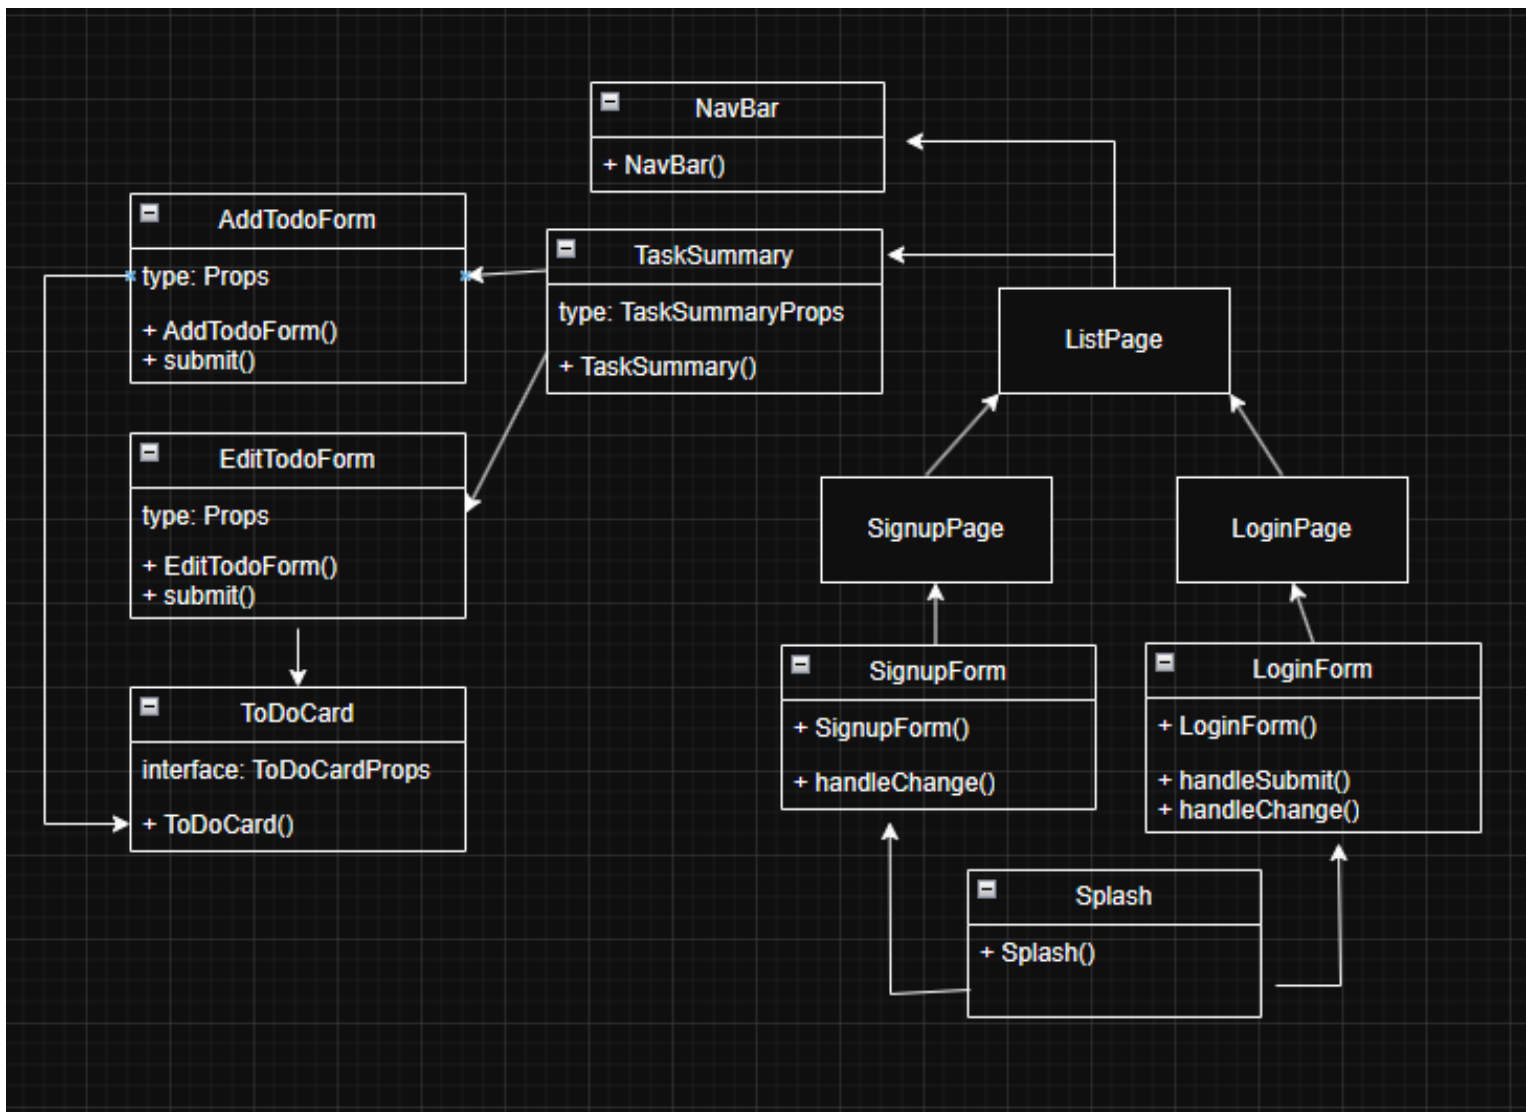

3.2 Mid-Level Design

The mid-level view expands the architecture into three core subsystems: Frontend, Backend, and Database. It also describes the responsibilities of each subsystem.

3.3 UML Class Diagram

This section includes the class-level view illustrating models, services, and key UI components and their attributes/operations.

3.4 Sequence Diagram

This diagram demonstrates the flow of data when a user creates a new task object in the application.
